## (54) COATING OF GLASS SURFACES

We, SAINT-GOBAIN INDUSTRIES, a Body Corporate organised under the laws of the French Republic, of 62 Boulevard Victor Hugo, 92209 Neuilly Sur Seine, France, do hereby declare the invention, for which we pray that a patent may be granted to us, and the method by which it is to be performed, to be particularly described in and by the following statement:-

The present invention relates to a method of making glass articles, including

flat glass sheets, coated with a film comprising titanium oxide.

It is known that flat glass covered with a film of metal oxide may be obtained by depositing on the glass heated to an elevated temperature a solution of metal acetyl acetonates to form a film of metal oxide of warm colour, the film being formed of a mixture of oxides chosen from cobalt oxide, chromium oxide and similar. oxides.

On the other hand there is also used a film of titanium oxide as a coloured coating of cold colour on flat glass, this film being obtained by atomising a solution of titanium acetyl acetonate on the glass heated to a high temperature. However the film of titanium oxide prepared by this method has the disadvantage of not being uniform when the film is too thin or too thick. In particular in the case of a thick film the inequalities in thickness may be visible to the naked eye and the film is often formed of irregular depositions. On the other hand the mechanical properties and chemical intertness of the film leave something to be desired.

The above mentioned faults render the flat glass obtained unsaleable as a heat

reflecting pane.

It has been found that the characteristics of thermal decomposition of the titanium chelates depend on the inertness of the compound to hydrolysis. Titanium acetyl acetonate, which has a high rate of hydrolysis, is decomposed at a relatively low temperature in comparison with other titanium compounds having a

low rate of hydrolysis. On the other hand the rate of thermal decomposition of titanium acetylacetonate is influenced only slightly by the temperature of the glass on which the solution is deposited and the effectiveness of the deposition on the glass to obtain a film of titanium oxide is very high, but the film obtained is not uniform and has mediocre mechanical properties and chemical intertness. Other experiments have shown that titanium tetraoctylene glycol and titanium triethanolamine, which are subject to hydrolysis at a much lower speed than other chelate compounds of titanium, have the disadvantage that the compounds are strongly influenced by the temperature of the glass regarding their efficiency of deposition in the form of titanium oxide. However these compounds provide extremely uniform films on the glass. Other experiments have also shown that titanium methyl acetoacetate and titanium ethylacetoacetate, of which the speeds of hydrolysis are intermediate between that of titanium acetyl acetonate and titanium tetraoctylene glycol and titanium triethanolamine, have intermediate values regarding the efficiency of deposition on the glass as well as a good film uniformity. From these results the applicant has developed a method allowing elimination of the above mentioned

disadvantages of titanium oxide films obtained from titanium acetylacetonate. According to the invention there is provided a method of applying a coating comprising titanium oxide to a glass surface, in which a solution containing at least two titanium compounds selected from titanium acetylacetonate, titanium methyl acetoacetate, titanium ethyl acet acetate, titanium tetraoctylene glycol and titanium triethanolamine is applied to the surface which is at an elevated

temperature sufficient to decompose the compounds to titanium oxide.

| _  |  |      |
|----|--|------|
|    | The solution preferably comprises an organic solvent having a boiling point of at least 100°C and capable of dissolving said titanium chelates.                        | .•   |
|    | The process of the invention may be applied t flat glass, glass bottles and  |      |
|    | other articles of glass. It may also be used in an effective manner on a ribbon of   |      |
| 5  | glass which is manufactured continuously starting from molten glass.   | 5    |
|    | To deposit the solution of titanium compounds it is preferable to operate by   |      |
|    | atomising said solution onto the glass heated to a high temperature. It is also pre-   |      |
|    | ferable in the present invention to pre-heat the flat glass to a high temperature and  |      |
| 10 | to maintain it at a temperature slightly lower until there is obtained on the glass a film of the desired thickness.   | 10   |
| 10 | Taking account of the deformation temperature of the glass it is advisable to  | . 10 |
|    | choose temperatures from 500 to 700°C.   |      |
|    | In the present invention it is possible to add to the solution containing  |      |
|    | titanium chelates, a metallic compound which is thermally decomposable to give a   | •    |
| 15 | coloured metallic oxide, such as cobalt oxide, iron oxide, nickel oxide or   | 1,5  |
|    | chromium oxide, but it is usually preferable to use a solution containing only the   | •    |
|    | chelate compounds of titanium when a layer containing titanium oxide only is   |      |
|    | desired.  In the use of the invention the solution of titanium compounds is prepared by  |      |
| 20 | adding to a solvent at least two compounds chosen among the five chelates of   | 20   |
| 20 | titanium mentioned above, the optimum composition of the solution being a func-  | 20   |
|    | tion of the operating conditions. The most advantageous composition may be   |      |
|    | chosen as a function of the glass temperature, its thermal capacity and the desired  |      |
|    | thickness of the film. For example when the temperature of the glass is relatively   |      |
| 25 | high and its thermal capacity is relatively large the use of a relatively large quantity   | 25   |
|    | of titanium tetraoctyleneglycol and/or titanium triethanolamine (which have a  |      |
|    | decomposition temperature which is relatively high) provides a film which is very  |      |
|    | strong and has an excellent uniformity. When the temperature of the glass is   |      |
| •• | relatively low and its thermal capacity is relatively small it is preferable to use a relatively large quantity of titanium acetylacetonate (which has a decomposition | 30   |
| 30 | temperature which is relatively low) in order to obtain a film of relatively large   | 30   |
|    | thickness.   |      |
|    | To obtain on the flat glass a reflecting power greater than 30% to visible light,  |      |
|    | it is preferable to use a relatively large quantity of titanium acetylacetonate which  |      |
| 35 | gives a high yield on deposition.  | 35   |
|    | In the present invention it is preferable to have in the solution at least 20% by  |      |
|    | volume of a titanium chelate other than the acetylacetonate to obtain a very strong  |      |
| •  | film having good uniformity.  It is also preferable according to the invention to dissolve the titanium  |      |
| 40 | chelates in an organic solvent to a concentration of 5 to 80% by volume. As an   | 40   |
| 40 | organic solvent there may be used many types of polar and non-polar solvents of  |      |
|    | various densities, viscosities and latent heats of evaporation but it is preferable to   |      |
|    | choose a solvent having a boiling point greater than 100°C. As solvent there may   |      |
|    | be mentioned the alcohols (such as normal butyl alcohol, iso-butyl alcohol, and  |      |
| 45 | normal amyl alcohol), the ketones (such as methyl-propyl-ketone, methyl-n-   | 45   |
| •  | butylketone, methyl-n-amylketone), esters (such as n-butyl acetate, isoamyl ace-   |      |
|    | tate, iso-propyl acetate), glycol ethers (such as ethylene glycol mono-ethyl-ether,  |      |
|    | ethylene glycol diethylether, ethylene glycol monobutyl ether), aromatic hydrocarbons (such as toluene, xylene), and compounds having a high boiling                   |      |
| 50 | point (such as diethylene glycol diethylether, diethylene glycol monobutylether).  | 50   |
| 50 | There may also be used as a solvent in the present invention, ligands formed by  |      |
|    | molecules entering into the composition of the titanium chelates such as acetyl  |      |
|    | acetone, methyl acetoacetate, ethyl acetoacetate, octylene glycol and triethanol-  |      |
|    | amine.   |      |
| 55 | In the use of the present invention, the solution containing at least two types  | 55   |
|    | of titanium chelate chosen among titanium acetylacetonate, titanium methyl-  |      |
|    | acetoacetate, titanium ethylacetoacetate, titanium tetraoctylene glycol and  |      |
|    | titanium triethanolamine, is atomised or otherwise deposited on the glass surface<br>heated to a high temperature to form a film of titanium oxide. The reason for     |      |
| 60 | obtaining a film of excellent uniformity has not yet been discovered but it is   | 60   |
|    | believed that the process proceeds in the following manner.  |      |
|    | During impact of a molecule of titanium chelat on the surface I glass heated   |      |
| -  | to a high temperature, a chemical bond between the ligand and the titanium is  |      |
|    | broken and the p lymerisation reaction of TiO proceeds at a high speed. For a  | 4-   |
| 65 | titanium compound having a low temperature of decomposition, the greatest part   | 65   |
|    |  |      |
|    |  |      |

| 2 | 1,510,587 |      |   |   |
|---|-----------|------|---|---|
| ) | 1,510,507 |      | - |   |
|   |           | <br> |   | _ |

| 3           | 1,00,007   | <del></del> _    |
|-------------|--|------------------|
| <del></del> | of a thermal decomposition reaction takes place in a very short interval f time  | —- <del></del> - |
|             | after impact of a dr plet on the surface of the glass which leads only to local for-   |                  |
|             | mation of the film. On the other hand for a titanium compound having a high  |                  |
|             | temperature of decomposition the thermal decomposition reaction starts immediately after impact of the droplets on the surface of the glass but it c n-          | c                |
| <b>5</b> .  | tinues for an appreciable duration of time during which the at mised droplets  | 5                |
|             | spread on the surface thus forming a uniform coating film.   |                  |
|             | On the other hand, for a titanium compound having a high temperature of  |                  |
|             | decomposition, it is considered that a reaction in the gaseous phase takes place at  |                  |
| 10          | the surface of the glass brought to a high temperature to give a coated film which is  | 10               |
| 10          | denser because such a chelate is not decomposed on the surface of the hot glass  |                  |
|             | but is present in the gaseous phase.   |                  |
|             | The process of the present invention may be applied to a film of glass formed  | •                |
|             | continuously starting from molten glass. In this process for treatment of glass con-   |                  |
| 15          | tinuously the solution of titanium compound is pulverised by means of a pulveris-  | 15               |
|             | ing device which is displaced transversely to the direction of advance of the glass  |                  |
|             | film brought to a high temperature. In this case the lack of uniformity of the coated film which would appear following displacement of the pulveriser may be    |                  |
| •           | eliminated and the portion of the film having a coating of uniform thickness   |                  |
| 20          | transversely to the ribbon increases so that the usable width of the coating is also   | 20               |
| 20          | increased.   | 20               |
|             | On the other hand, given that in the process of the present invention there is   |                  |
|             | used at least two types of titanium compound which have different characteristics  |                  |
|             | of thermal decomposition the choice of the composition of the solution of  |                  |
| 25          | titanium compounds ensures constant conditions which are stable for formation of   | 25               |
|             | the coated film independently of the thermal conditions of the sheet of glass and its  |                  |
|             | thickness. Further, the use of titanium chelates at a concentration from 5 to 80%  |                  |
|             | by volume in an organic solvent easily leads to the formation of a coated film   |                  |
|             | having good mechanical properties, a large chemical inertness and a uniform thick-   |                  |
| 30          | ness. When there is dissolved in the solution a quantity of titanium chelate greater   | 30               |
|             | than 80% by volume the viscosity of the solution increases so that pulverisation becomes difficult and the number and dimensions of the titanium oxide particles |                  |
|             | formed in the coated film increase which can give a defective appearance to the  |                  |
|             | film. Further if there is dissolved less than 5% by volume of the titanium chelate in  |                  |
| 35          | the solution, a large part of the solvent has the effect of cooling the pre-heated sur-  | 35               |
| -           | face of the glass so that the film is then formed at a low temperature. The film   |                  |
|             | obtained may then have mediocre properties (mechanical properties and chemical   |                  |
|             | inertness).  |                  |
|             | When there is used an organic solvent having a boiling point greater than  |                  |
| 40          | 100°C the dimensions of the titanium oxide particles formed are generally so small   | 40               |
| •           | that they are invisible to the naked eye which considerably improves the unifor-   |                  |
|             | mity of the film. In use of the invention it is possible to add to the solution of   |                  |
|             | titanium chelate a thermally decomposable metal compound to form a coloured metal oxide which allows production starting from the solution, of a coloured        |                  |
| 45          | film containing titanium oxide and said coloured metal oxide.  | 45               |
| 43          | Preferred embodiments of the invention will be described in the following  | 43               |
|             | Examples. "Reference samples" are given by way of comparison.  |                  |
|             |  |                  |
|             | EXAMPLE 1.   |                  |
|             | A solution of titanium chelate was sprayed at the outlet of a furnace for  |                  |
| 50          | manufacturing flat glass by flotation on a bath of molten metal on to the glass rib-   | 50               |
|             | bon obtained (dimensions of the glass ribbon 3 m width and 6 mm thickness).  |                  |
|             | The glass left the furnace at 580°C and was displaced at a speed of 3.2 m per  |                  |
|             | minute. Spraying was carried out under a pressure of 4 kg/cm² with a sprayer which   |                  |
| 55          | was displaced in to and fro movement perpendicular to the direction of advance of  |                  |
| <i>33</i>   | the glass ribbon.  The ribbon coated with a solution forming the titanium oxide film was passed  | 55               |
|             | through a re-heating enclosure and after re-cooling it was cut.  |                  |
|             | The solution of titanium chelate which was pulverised on the glass surface   |                  |
|             | was composed of:   |                  |
| 60          | — 30 cm <sup>3</sup> of titanium acetylacetonate   | 60               |
|             | — 20 cm³ of tetraoctylene glycol titanate  | •                |
|             | and  |                  |
|             | — 50 cm³ of xylene.  |                  |
|             | By means of this s lution there was prepared sample No. 1.   |                  |
|             |  |                  |

| ,  |   |      |
|----|---|------|
| 5  | EXAMPLE 2.  A sample 2 was prepared using a solution of titanium chelate formed of 35 cm <sup>3</sup> of titanium acetylacetonate, 15 cm <sup>3</sup> of titanium tetraethanolamine, 25 cm <sup>3</sup> of xylene and 25 cm <sup>3</sup> of isoamyl acetate, the spraying conditions being the same as in Example 1.  The sample 2 has approximately the same optical characteristics as those of sample 1 and it has a mechanical and chemical resistance and also a uniformity of film greater than those of the reference sample 1 as will be seen in Table 1. | 5    |
| 10 | EXAMPLE 3.  A sample 3 was prepared using a solution of titanium chelate formed of 30 cm <sup>3</sup> of titanium methyl acetoacetate 20 cm <sup>3</sup> of titanium tetraoctylene glycol and 50 cm <sup>3</sup>  | 10   |
| 15 | of xylene. The spraying conditions are the same as in Example 1.  The sample 3 has approximately the same optical characteristics as the sample 1 and it has properties of mechanical strength and chemical inertness and uniformity of film superior to those of reference sample 1 as will be seen in Table 1.  | 15   |
| 20 | EXAMPLE 4.  The sample 4 is obtained using a solution of titanium chelate formed of 35 cm <sup>3</sup> of titanium ethylacetoacetate, 15 cm <sup>3</sup> of titanium tetraoctylene glycol and 50 cm <sup>3</sup> of xylene. The spraying conditions are the same as in Example 1.  The sample 4 has approximately the same optical characteristics as those of sample 1 and it has properties of mechanical strength, chemical inertness and film uniformity superior to those of the sample of reference 1 as seen in Table 1.                                   | 20   |
| 25 | EXAMPLE 5.  The sample 5 is prepared using a solution of titanium chelate compound of 15 cm³ of titanium acetylacetonate, 15 cm³ of titanium ethyl acetoacetate, 20 cm³ of titanium tetraoctylene glycol and as solvent a mixture of 25 cm³ of xylene and 25 cm³ of butanol.  | 25   |
| 30 | The spraying conditions are the same as in Example 1.  The sample 5 has approximately the same optical characteristics as those of sample 1 and it has properties of mechanical strength, chemical inertness and film uniformity which are superior to those of reference sample 1 as seen in Table 1.  | 30   |
| 35 | EXAMPLE 6.  The sample 6 is prepared using a titanium chelate solution formed of 25 cm³ of titanium acetylacetonate, 25 cm³ of titanium ethyl acetoacetate and 50 cm³ of xylene.  The spraying conditions are the same as in Example 1.  The sample 6 has the same optical characteristics as those of sample 1 and it has properties of mechanical strength, chemical inertness and film uniformity  | 35   |
| 40 | superior to those of reference sample 1 as seen in Table 1.   | 40.  |
| 45 | EXAMPLE 7.  The sample 7 is prepared using a solution of titanium chelate formed of 15 cm <sup>3</sup> of titanium methyl acetoacetate, 20 cm <sup>3</sup> of titanium ethylacetoacetate and 65 cm <sup>3</sup> of xylene. The spraying conditions are the same as in Example 1.  The sample 7 has approximately the same optical characteristics as those of sample 1 and it has properties of mechanical strength, chemical inertness and film uniformity superior to those of reference sample 1 as seen in Table 1.   | 45   |
| 50 | EXAMPLE 8.  At the output of a chamber for manufacture of glass floating on a bath of molten metal, there is sprayed a solution of titanium chelates on a glass ribbon of which the dimensions are about 3 m width and 10 mm thickness. The glass ribbon is heated at 580°C and is displaced at a speed of 3.2 metres per minute. Spraying is carried out at a pressure of 4 kg/cm² by means of a sprayer which is displaced in to  | . 50 |
| 55 | and fro movement transversely to the direction of advance of the glass ribbon; the surface of the glass is covered with a solution which forms a titanium oxide film, the ribbon then being passed in a re-heating enclosure and cut up after cooling.  The solution of titanium chelate which is pulverised on the surface of the glass is formed of 30 cm³ of titanium acetylacetonate, 15 cm³ f titanium tetraoctylene glycol and 55 cm³ f xylene as a solvent.  | 55   |

| U  |   |         |
|----|---|---------|
|    | A sample 8 is prepared. The optical characteristics of this sample are approximately the same as those of sample 1. The properties of mechanical strength, chemical inertness and uniformity of film are also indicated in Table 1.  By way of comparison there is prepared a reference sample 2 using the same   | c       |
| 5  | conditions of spraying as in Example 8, but using as the solution of thanium chelate a mixture of 50 cm³ of titanium acetylacetonate and 50 cm³ of xylene as solvent. The reference sample 2 has the same optical characteristics as those of sample 2 but the reference sample 2 gives inferior results regarding the mechanical strength and chemical inertness and also uniformity of film in comparison with  | 5<br>10 |
|    | sample 8 as appears from Table 1.  After the preceding trails, it is apparent that the glass coated with a film of titanium oxide according to the method of the present invention, has characteristics of mechanical strength, chemical inertness and film uniformity superior to those of the film prepared by the known process.   |         |
| 15 | EXAMPLE 9.  There is placed a sheet of float glass (30 cm × 30 cm × 5 mm) in an electric furnace heated at 670°.  | 15      |
| 20 | The sample is left for 4 minutes in the furnace and then is removed and there is sprayed on the hot glass plate a solution of titanium chelate described below with a feed of 25 cm <sup>2</sup> /mn for 8 to 10 seconds at a pressure of 3 kg/cm <sup>2</sup> using a sprayer (registered trake mark WIDER 60).  There is thus obtained a glass plate covered with a film having a reflective  | 20      |
| 25 | power of about 33% for visible light. Each spraying solution is formed of 30 cm <sup>3</sup> of titanium acetylacetonate, 20 cm <sup>3</sup> of titanium tetraoctylene glycol and 50 cm <sup>3</sup> of one of the organic solvents listed in Table 2.  Each time the appearance of the titanium oxide film thus produced is estimated by examining with the naked eye the particles of titanium oxide in the film and counting the particles by means of a microscope. The appearance of the | 25      |
| 30 | film thus obtained is thus indicated in Table 2. As will be seen from the Table there is always obtained a film of excellent uniformity if there is used an organic solvent having a boiling point of greater than 100°C.   | 30      |

EXAMPLE 10.

There is deposited by a spraying as in Example 9 various solutions of titanium chelates on glass plates which are heated to produce a film of titanium oxide.

Each spraying solution used is formed of 40 cm³ of titanium methylaceto-acetate and 10 cm³ of titanium tetraoctylene glycol dissolved in 50 cm³ of one of the organic solvents mentioned in Table 3.

There is observed each time the appearance of film of titanium oxide and the possible presence of titanium oxide particles in the same way as in Example 9.

The results are indicated in Table 3.

As will be seen, the film has excellent uniformity when the organic solvent

As will be seen, the film has excellent uniformity when the organic solvent used has a boiling point greater than 100°C.

EXAMPLE 11.

On glass plates heated in the same conditions as Example 9 there were deposited various solutions of titanium chelates to produce films of titanium oxide. Each spraying solution is formed of 30 cm³ of titanium ethylacetoacetat and 20 cm³ of titanium tetraoctylene glycol dissolved in 50 cm³ of one of the solv nts f Table 4. There is observed the appearance of the film and especially the presence of titanium oxide in the same manner as in Example 9. The results are shown in Table 4. As will be seen in the Table there is obtained a film of excellent uniformity when there is used a solvent having a boiling point greater than 100°C.

EXAMPLE 13.

On glass plates which are heated there is sprayed by the process of Example 9 various solutions of titanium chelate in order to produce a film of titanium oxide on the glass. Each spraying solution used is formed of 30 cm³ titanium acetylacetonate, 20 cm³ of tetraoctylene glycol titanium, 3 grams of iron acetylacetonate, 3 grams of chromium acetylacetonate and 50 cm³ of one of the solvents of Table 6. The properties of the film and the possible presence of titanium oxide particles are observed in the same way as in Example 9. The results are indicated in Table 6 in which it is possible to see that the film has excellent properties of uniformity when the solvent used has a boiling point greater than 100°C.

As will appear from the description above, owing to the process of the invention, there is avoided the adhesion of titanium oxide particles on the coating film and there is no alteration in the good appearance of the film of titanium oxide.

WHAT WE CLAIM IS:—

1. A method of applying a coating comprising titanium oxide to a glass surface, in which a solution containing at least two titanium compounds selected from titanium acetylacetonate, titanium methyl acetoacetate, titanium ethyl acetoacetate, titanium tetraoctylene glycol and titanium triethanolamine is applied to the surface which is at an elevated temperature sufficient to decompose the compounds to titanium oxide.

2. A method according to Claim 1, in which the solution comprises an organic solvent having a boiling point of at least 100°C.

3. A method according to either preceding claim, in which the temperature of the surface is from 500° to 700°C.

4. A method according to any preceding claim, in which the solution is sprayed on to the surface.

5. A method according to Claim 4, in which the solution is sprayed on to a surface of a ribbon of glass prepared by the float glass process.

6. A method according to any preceding claim, in which the solution contains from 5 to 80% by volume of said titanium compounds.

|    | 7. A method according to any preceding claim, in which the solution contains at least 20% by volume of said titanium compounds other than titanium acetyl- |      |
|----|--|------|
|    | acet nate.  8. A method according to any preceding claim, in which the solution contains   |      |
| 5  | a compound of a metal ther than titanium capable of forming an oxide of said   | 5    |
|    | metal on heating.  |      |
|    | 9. A method of applying a coating comprising titanium oxide to a glass surface, substantially as hereinbefore described with reference to the Examples.    |      |
|    | 10. Glass articles provided with a titanium oxide coating applied by a method  |      |
| 10 | according to any preceding claim.  | . 10 |
